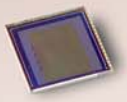
OmniVision



datasheet

PRELIMINARY SPECIFICATION

1/4" color CMOS QSXGA (5 megapixel) image sensor
with OmniBSI™ technology

OV5647

color CMOS QSXGA (5 megapixel) image sensor with OmniBSI™ technology

datasheet (COB)
PRELIMINARY SPECIFICATION

version 1.0
november 2009

To learn more about OmniVision Technologies, visit www.ovt.com.
OmniVision Technologies is publicly traded on NASDAQ under the symbol OVTI.

applications

- cellular phones
- toys
- PC multimedia
- digital still cameras

ordering information

- **OV05647-G04A** (color, chip probing, 200 µm backgrinding, reconstructed wafer)

features

- 1.4 µm x 1.4 µm pixel with OmniBSI technology for high performance (high sensitivity, low crosstalk, low noise)
- optical size of 1/4"
- automatic image control functions: automatic exposure control (AEC), automatic white balance (AWB), automatic band filter (ABF), automatic 50/60 Hz luminance detection, and automatic black level calibration (ABLC)
- programmable controls for frame rate, AEC/AGC 16-zone size/position/weight control, mirror and flip, cropping, windowing, and panning
- image quality controls: lens correction, defective pixel canceling
- support for output formats: 8-/10-bit raw RGB data
- support for video or snapshot operations
- support for LED and flash strobe mode
- support for internal and external frame synchronization for frame exposure mode
- support for horizontal and vertical sub-sampling
- standard serial SCCB interface
- digital video port (DVP) parallel output interface
- MIPI interface (two lanes)
- 32 bytes of embedded one-time programmable (OTP) memory
- on-chip phase lock loop (PLL)
- embedded 1.5V regulator for core power
- programmable I/O drive capability, I/O tri-state configurability
- support for black sun cancellation

key specifications

- **active array size:** 2592 x 1944
- **power supply:**
  core: 1.5V ± 5% (with embedded 1.5V regulator)
  analog: 2.6 ~ 3.0V (2.8V typical)
  I/O: 1.7V ~ 3.0V
- **power requirements:**
  active: TBD
  standby: TBD
- **temperature range:**
  operating: -30°C to 70°C (see **table 8-2**)
  stable image: 0°C to 50°C (see **table 8-2**)
- **output formats:** 8-/10-bit RGB RAW output
- **lens size:** 1/4"
- **lens chief ray angle:** 24° (see **figure 10-2**)
- **input clock frequency:** 6~27 MHz
- **S/N ratio:** TBD
- **dynamic range:** TBD
- **maximum image transfer rate:**
  QSXGA (2592 x 1944): 15 fps
  1080p: 30 fps
  960p: 45 fps
  720p: 60 fps
  VGA (640 x 480): 90 fps
  QVGA (320 x 240): 120 fps
- **sensitivity:** TBD
- **shutter:** rolling shutter / global shutter
- **maximum exposure interval:** 1968 x t_{ROW}
- **pixel size:** 1.4 µm x 1.4 µm
- **well capacity:** TBD
- **dark current:** TBD
- **fixed pattern noise (FPN):** TBD
- **image area:** 3673.6 µm x 2738.4 µm
- **die dimensions:** 5520 µm x 4700 µm

1 signal descriptions

table 1-1 lists the signal descriptions and their corresponding pad numbers for the OV5647 image sensor. The die information is shown in **section 9**.

table 1-1 signal descriptions (sheet 1 of 2)

pad number	signal name	pad type	description
1	AVDD	power	power for analog circuit, 2.8V
2	AGND	power	ground for analog circuit
3	DOGND	power	ground for digital I/O
4	SCL	input	SCCB clock input
5	SDA	I/O	SCCB data I/O
6	DVDD	power	power for digital core circuit, 1.5V (connect to 0.1uF capacitor to ground)
7	SGND	power	ground for pixel array
8	GPIO1	I/O	GPIO 1
9	GPIO0	I/O	GPIO 0
10	STROBE	I/O	strobe output
11	FREX	I/O	frame exposure control
12	DOVDD	power	power for digital I/O, 1.7 ~ 3.0V
13	VREF2	reference	reference analog circuit (connect to 0.1uF capacitor to ground)
14	VREF1	reference	reference for analog circuit (connect to 0.1uF capacitor to ground)
15	PWDN	input	power down control (active high with internal pull-down resistor)
16	DVDD	power	power for digital core circuit, 1.5V (connect to 0.1uF capacitor to ground)
17	RESETB	input	hardware reset (active low with internal pull-up resistor)
18	AVDD	power	power for analog circuit, 2.8V
19	AGND	power	ground for analog circuit
20	TM	input	test mode (active high with internal pull down resistor)
21	DOGND	power	ground for digital I/O
22	DVDD	power	power for digital core circuit, 1.5V (connect to 0.1uF capacitor to ground)

table 1-1 signal descriptions (sheet 2 of 2)

pad number	signal name	pad type	description
23	DVDD	power	power for digital core circuit, 1.5V (connect to 0.1uF capacitor to ground)
24	DOVDD	power	power for digital I/O, 1.7 ~ 3.0V
25	DOGND	power	ground for digital I/O
26	AVDD	power	power for analog circuit, 2.8V
27	HREF	I/O	DVP HREF output
28	PCLK	I/O	DVP PCLK output
29	VSYNC	I/O	DVP VSYNC output
30	DOVDD	power	power for digital I/O, 1.7 ~ 3.0V
31	D0	I/O	DVP data bit 0
32	D1	I/O	DVP data bit 1
33	D2	I/O	DVP data bit 2
34	D3	I/O	DVP data bit 3

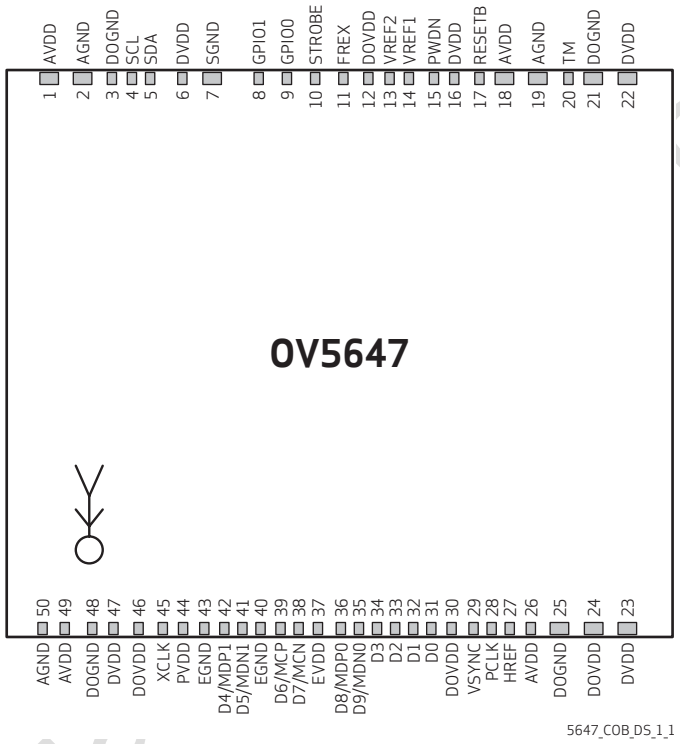
a. some customer assume PWDN pin = 1 when chip power up

b. PWDN pin = 0 when chip power up

figure 1-1 pad diagram



2 system level description

2.1 overview

The OV5647 is a low voltage, high performance, 5 megapixel CMOS image sensor that provides 2592x1944 video output using OmniBSI™ technology. It provides multiple resolution raw images via the control of the serial camera control bus or MIPI interface.

The OV5647 has an image array capable of operating up to 15 fps in 2592x1944 resolution with user control of image quality, data transfer, camera functions through the SCCB interface. The OV5647 uses innovative OmniBSI technology to improve the sensor performance without the physical and optical trade-off.

For customized application, the OV5647 includes a one-time programmable (OTP) memory.

2.2 architecture

The OV5647 sensor core generates streaming pixel data at a constant frame rate, indicated by HREF and VSYNC. **figure 2-1** shows the functional block of the OV5647 image sensor. **figure 2-2** shows an example application of the OV5647 sensor.

figure 2-1 OV5647 block diagram

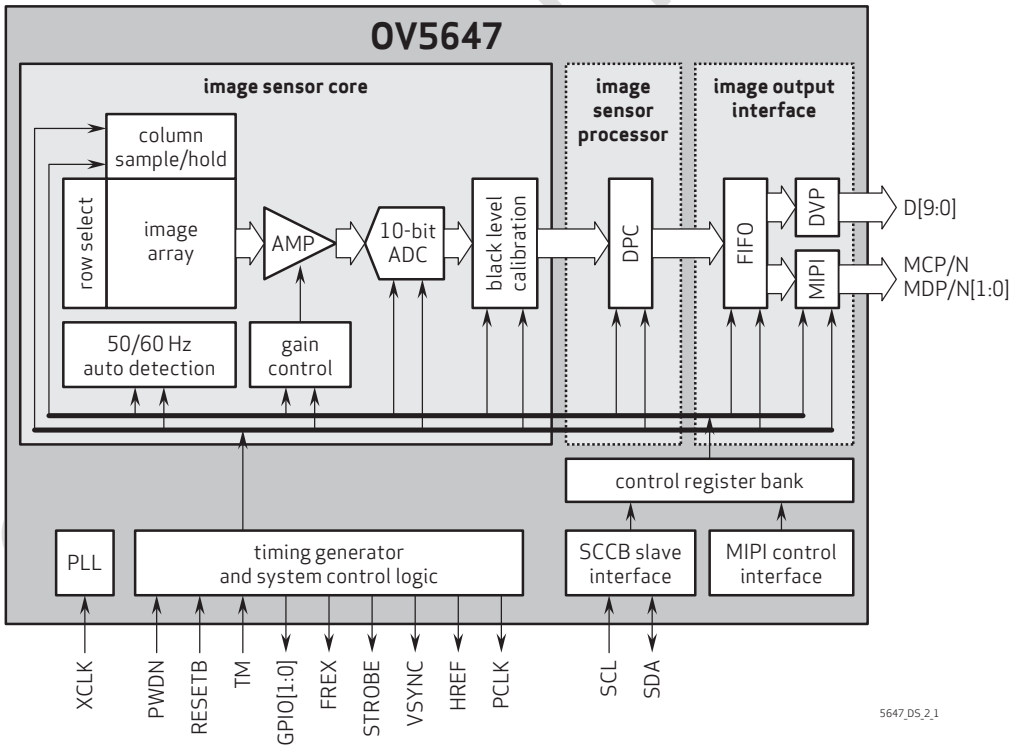


figure 2-2 reference design schematic

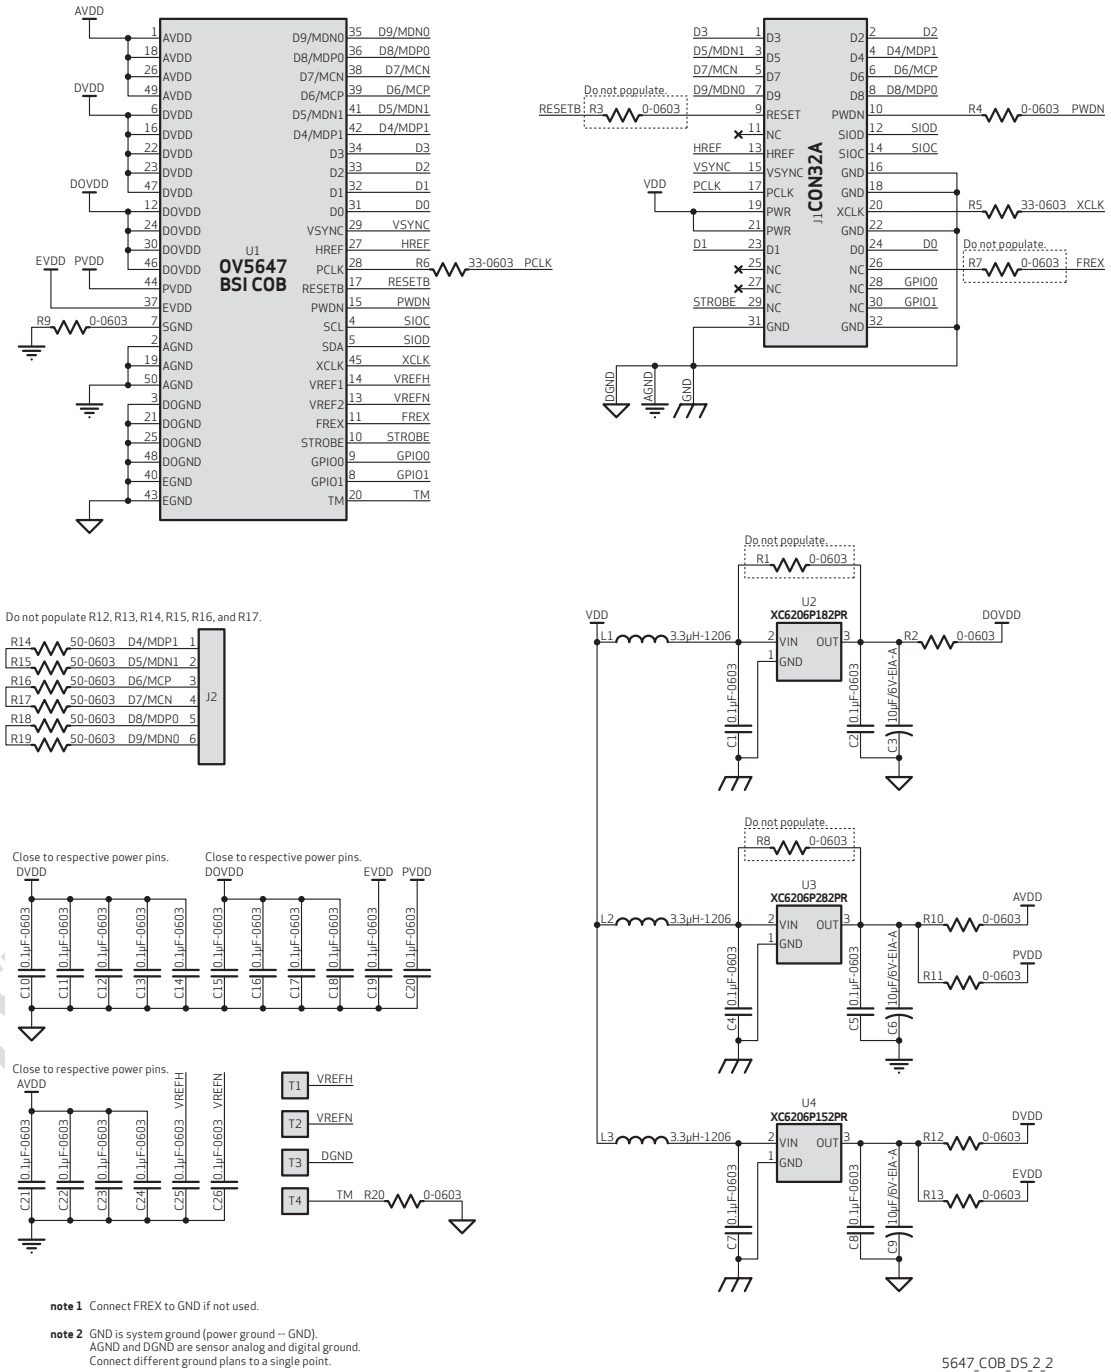


note 1 Connect FREX to GND if not used.

note 2 GND is system ground (power ground -- GND).
AGND and DGND are sensor analog and digital ground.
Connect different ground plans to a single point.

5647_COB_DS_2_2

2.3 format and frame rate

table 2-1 format and frame rate

format	resolution	frame rate	scaling method	pixel clock
5 Mpixel	2592x1944	15 fps	full resolution	80 MHz
1080p	1920x1080	30 fps	cropping	68 MHz
960p	1280x960	45 fps	cropping, subsampling/ binning	91.2 MHz
720p	1280x720	60 fps	cropping, subsampling/ binning	92 MHz
VGA	640x480	90 fps	cropping, subsampling/ binning	46.5 MHz
QVGA	320x240	120 fps	cropping, subsampling/ binning	32.5 MHz

2.4 I/O control

2.4.1 system clock control

The PLL is inside the chip which generates a default 96 MHz clock from 6~27 MHz input clock. An inside programmable clock divider is used to generate different frame rate timing.

2.5 power up sequence

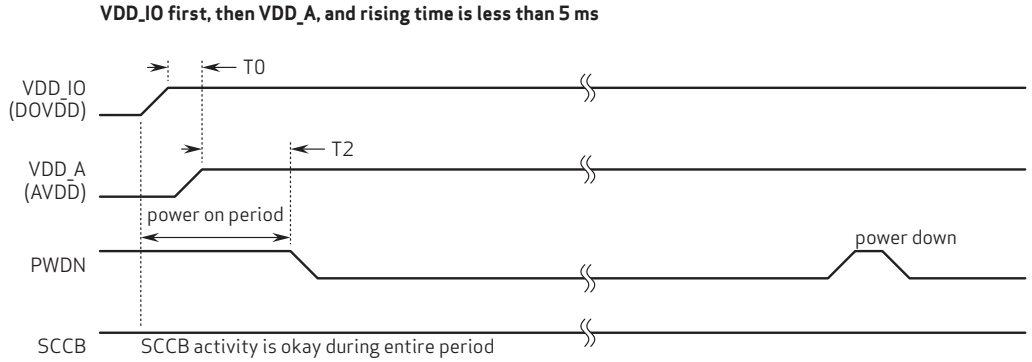
Based on the system power configuration (1.8V or 2.8V for I/O power), using external DVDD or internal DVDD, the power up sequence will differ. If 1.8V is used for I/O power, using the internal DVDD is preferred. If 2.8V is used for I/O power, due to a high voltage drop at the internal DVDD regulator, there is a potential heat issue. Hence, for a 2.8V power system, OmniVision recommends using an external DVDD source. Due to the higher power down current when using an external DVDD source, OmniVision strongly recommends cutting off all power supplies, including the external DVDD, when the sensor is not in use in the case of 2.8V I/O and external DVDD.

2.5.1 power up with internal DVDD

For powering up with the internal DVDD and SCCB access during the power ON period, the following conditions must occur:

1. if V_{DD-IO} and V_{DD-A} are turned ON at the same time, make sure V_{DD-IO} becomes stable before V_{DD-A} becomes stable
2. PWDN is active high with an asynchronized design (does not need clock)
3. PWDN must go high during the power up period
4. for PWDN to go low, power must first become stable (AVDD to PWDN $\geq$ 5 ms)
5. RESETB is active low with an asynchronized design
6. state of RESETB does not matter during power up period once DOVDD is up
7. master clock XCLK should provide at least 1 ms before host accesses sensor's SCCB
8. host can access SCCB bus (if shared) during entire period. 20 ms after PWDN goes low or 20 ms after RESETB goes high if reset is inserted after PWDN goes low, host can access sensor's SCCB to initialize sensor

figure 2-3 power up timing with internal DVDD



note T0 ≥ 0 ms: delay from VDD_IO stable to VDD_A stable
T2 ≥ 5 ms: delay from VDD_A stable to sensor power up stable

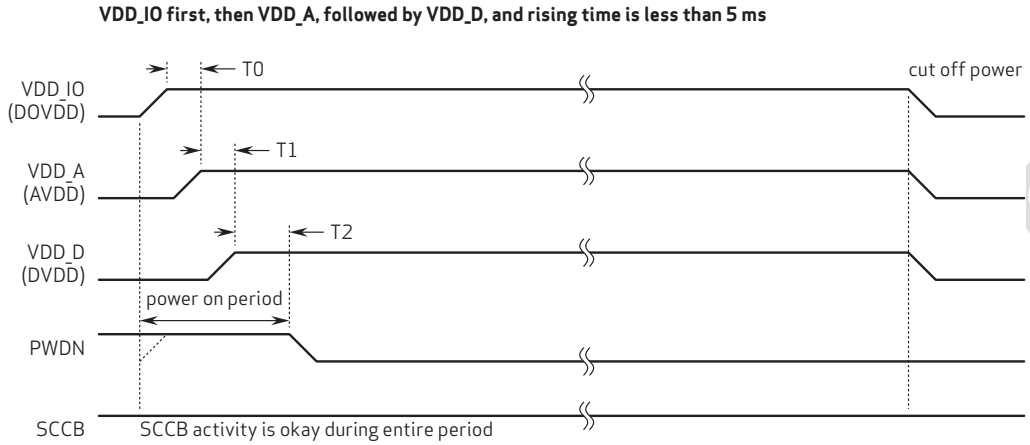
5647_DS_2_3

2.5.2 power up with external DVDD source

For powering up with an external DVDD source and SCCB access during the power ON period, the following conditions must occur:

1. if V_{DD-IO} and V_{DD-A} are turned ON at the same time, make sure V_{DD-IO} becomes stable before V_{DD-A} becomes stable
2. if V_{DD-A} and V_{DD-D} are turned ON at the same time, make sure V_{DD-A} becomes stable before V_{DD-D} becomes stable
3. PWDN is active high with an asynchronized design (does not need clock)
4. for PWDN to go low, power must first become stable (DVDD to PWDN ≥ 5 ms)
5. all powers are cut off when the camera is not in use (power down mode is not recommended
6. RESETB is active low with an asynchronized design
7. state of RESETB does not matter during power up period once DOVDD is up
8. master clock XVCLK should provide at least 1 ms before host accesses sensor's SCCB
9. host can access SCCB bus (if shared) during entire period. 20 ms after PWDN goes low or 20 ms after RESETB goes high if reset is inserted after PWDN goes high, host can access sensor's SCCB to initialize sensor

figure 2-4 power up timing with external DVDD source



note T0 ≥ 0 ms: delay from VDD_IO stable to VDD_A stable
T1 ≥ 0 ms: delay from VDD_A stable to VDD_D stable
T2 ≥ 5 ms: delay from VDD_D stable to sensor power up stable

5647_DS_2_4

2.6 reset

Two reset modes are available for the OV5647:

- hardware reset
- SCCB software reset

The OV5647 sensor includes a **RESETB** pad that forces a complete hardware reset when it is pulled low (GND). The OV5647 clears all registers and resets them to their default values when a hardware reset occurs. A reset can also be initiated through the SCCB interface by setting register 0x0103[0] to high.

The whole chip will be reset during power up. Manually applying a hard reset upon power up is recommended even though the on-chip power up reset is included. The hard reset is active low with an asynchronized design. The reset pulse width should be greater than or equal to 1 ms.

2.7 standby and sleep

Two suspend modes are available for the OV5647:

- hardware standby
- SCCB software sleep

To initiate hardware standby mode, the **PWDN** pad must be tied to high. When this occurs, the OV5647 internal device clock is halted and all internal counters are reset and registers are maintained. Executing a software sleep (0x0100[0]) through the SCCB interface suspends internal circuit activity but does not halt the device clock. All register content is maintained in both modes.

3 block level description

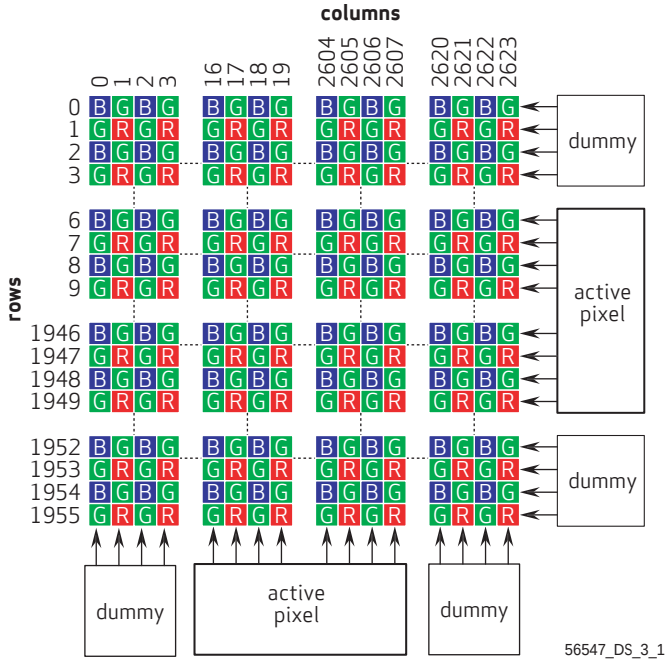
3.1 pixel array structure

The OV5647 sensor has an image array of 2624 columns by 1956 rows (5,132,544 pixels). **figure 3-1** shows a cross-section of the image sensor array.

The color filters are arranged in a Bayer pattern. The primary color BG/GR array is arranged in line-alternating fashion. Of the 5,132,544 pixels, 5,038,848 (2592x1944) are active pixels and can be output. The other pixels are used for black level calibration and interpolation. The center 2592x1944 is suggested to be output from the whole active pixel array. The backend processor can use the boundary pixels for additional processing.

The sensor array design is based on a field integration read-out system with line-by-line transfer and an electronic shutter with a synchronous pixel read-out scheme.

figure 3-1 sensor array region color filter layout



3.2 binning

The OV5647 supports 2x2 binning for better SNR in low light conditions. See **table 3-1** for horizontal and vertical binning registers.

signal to noise ratio

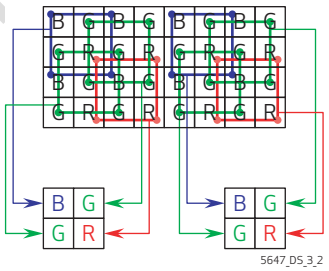
table 3-1 horizontal and vertical binning registers

address	register name	default value	R/W	description
0x3820	TIMING_TC_REG20	0x40	RW	Bit[0]: Vertical binning 0: Disable 1: Enable
0x3821	TIMING_TC_REG21	0x00	RW	Bit[0]: Horizontal binning 0: Disable 1: Enable

Sub-sampling is necessary when using binning.

Sensor timing adjustment is necessary after applying binning. Please consult your local OmniVision FAE for details.

figure 3-2 example of 2x2 binning



3.3 analog amplifier

When the column sample/hold circuit has sampled one row of pixels, the pixel data will shift out one-by-one into an analog amplifier.

3.4 10-bit A/D converters

The balanced signal is then digitized by the on-chip 10-bit ADC. It can operate at up to 27 MHz and is fully synchronous to the pixel clock. The actual conversion rate is determined by the frame rate.

4 image sensor core digital functions

4.1 mirror and flip

The OV5647 provides mirror and flip read-out modes, which respectively reverse the sensor data read-out order horizontally and vertically (see **figure 4-1**). In flip mode, the OV5647 does not need additional settings because the ISP block will auto-detect whether the pixel is in the red line or blue line and make the necessary adjustments.

figure 4-1 mirror and flip samples

original image | mirrored image | flipped image | mirrored and flipped image

5647_DS_4_1

table 4-1 mirror flip control registers

address	register name	default value	R/W	description
0x3820	TIMING_TC_REG20	0x40	RW	Timing Control Bit[2]: r_vflip_isp Bit[1]: r_vflip_snr
0x3821	TIMING_TC_REG20	0x00	RW	Timing Control Bit[2]: r_mirror_isp Bit[1]: r_mirror_snr

4.2 image windowing

An image windowing area is defined by four parameters, x_addr_start, x_addr_end, y_addr_start, y_addr_end. By properly setting the parameters, any portion or size within the sensor array can be defined as an visible area. This windowing is achieved by simply masking the pixels outside the defined window; thus, it will not affect the original timing.

figure 4-2 image windowing

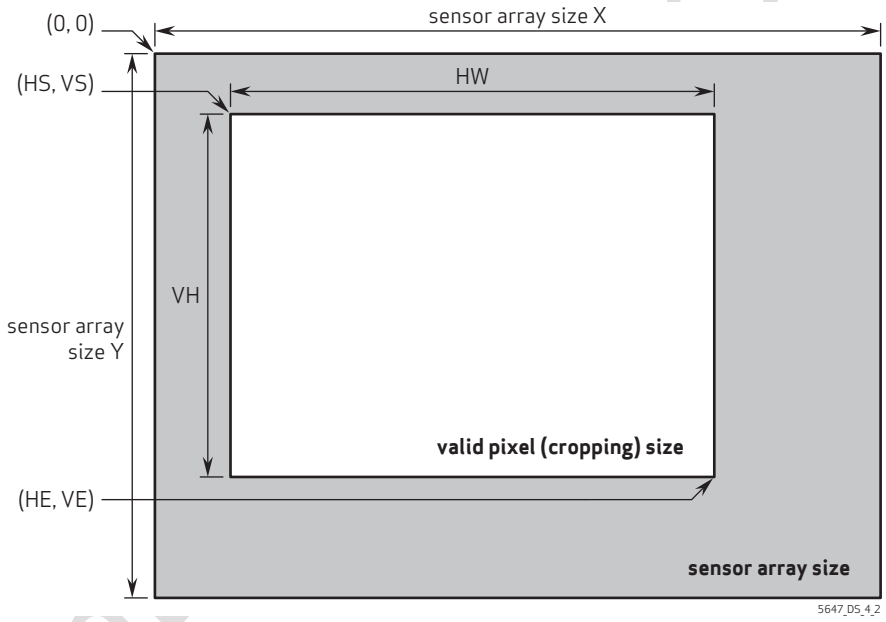


table 4-2 image windowing registers

address	register name	default value	R/W	description
0x3800	TIMING_X_ADDR_START	0x00	RW	Bit[3:0]: x_addr_start[11:8]

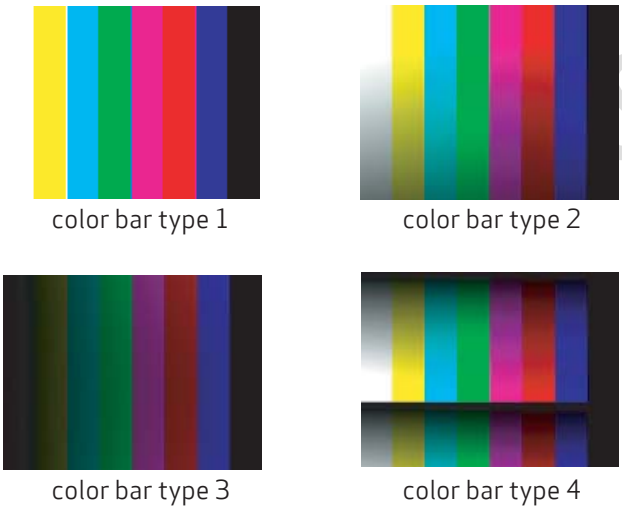
4.3 test pattern

For testing purposes, the OV5647 offers three types of test patterns, color bar, square and random data.The OV5647 also offers two effects: transparent effect and rolling bar effect. The output type of test pattern is controlled by register 0x503D[1:0] register (test_pattern_type).

4.3.1 color bar

There are four types of color bars shown in **figure 4-3**. The output type of color the color bar can be selected by bar style register 0x503D[3:2].

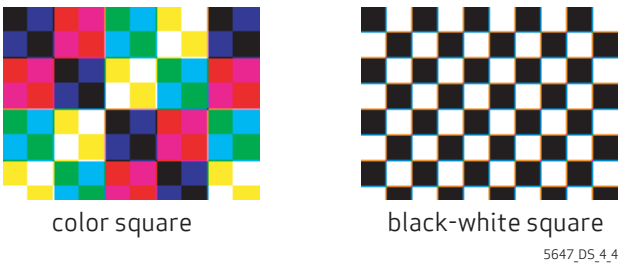
figure 4-3 color bar types



4.3.2 square

There are two types of square: color square and black-white square. Register 0x503D[4] (squ_bw) determines which type of square will be output.

figure 4-4 color, black and white square bars



4.3.3 random data

There are two types of random data test pattern: frame-changing and frame-fixed random data. The output type of random data is decided by register 0x503E[4] (rnd_same). The random seed is set by register 0x503E[3:0] (rnd_seed).

4.3.4 transparent effect

The transparent effect is enabled by register 0x503D[5] (transparent_mode). If this register is set, the transparent test pattern will be gotten. **figure 4-5** is a example which shows a transparent color bar image.

figure 4-5 transparent effect

5647_DS_4_5

4.3.5 rolling bar effect

The rolling bar is set by register 0x503D[6] (rolling_bar). If it is set, an inverted-color rolling bar will roll from up to down. **figure 4-6** is a example which shows a rolling bar on color bar image.

figure 4-6 rolling bar effect

4.4 50/60Hz detection

When the integration time is not an integer multiple of the period of light intensity, the image will flicker. The function of the detector is to detect whether the sensor is under a 50 Hz or 60 Hz light source so that the basic step of integration time can be determined. Contact your local OmniVision FAE for auto detection settings.

4.5 AEC and AGC algorithms

4.5.1 overview

The Auto Exposure Control (AEC) and Auto Gain Control (AGC) allows the image sensor to adjust the image brightness to a desired range by setting the proper exposure time and gain applied to the image. Besides automatic control, exposure time and gain can be set manually from external control. The related registers are listed in **table 4-5**

table 4-5 AEC/AGC control function registers

4.5.2 average-based algorithm

The average-based AEC controls image luminance using registers **WPT** (0x3A0F), **BPT** (0x3A10), **WPT2** (0x3A1B), and **BPT2** (0x3A1E). In average-based mode, the value of register **WPT** (0x3A0F) indicates the high threshold value for image change from unstable to stable state, and the value of register **BPT** (0x3A10) indicates the low threshold value for image change from unstable to stable state. The value of register **WPT2** (0x3A1B) indicates the high threshold value for image change from stable state to unstable state and the value of register **BPT2** (0x3A1E) indicates the low threshold value for image change from stable state to unstable state. When the target image luminance average value AVG (0x5693) is within the range specified by registers **WPT2** (0x3A1B) and **BPT2** (0x3A1E), the AEC keeps the image exposure and gain. When register AVG (0x5693) is greater than the value in register **WPT2** (0x3A1B), the AEC will decrease the image exposure and gain until it falls into the range of {0x3A10, 0x3A0F}. When register AVG (0x5693) is less than the value in register **BPT2** (0x3A1E), the AEC will increase the image exposure and gain until it falls into the range of {0x3A10, 0x3A0F}. Accordingly, the value in register **WPT** (0x3A0F) should be greater than the value in register **BPT** (0x3A10). The value of register **WPT2** should be no less than the value of register **WPT**(0x3A0F), and the value of register **BPT2** (0x3A1E) should be no greater than the value of **BPT** (0x3A10).

The AEC function supports both manual and auto speed selections in order to bring the image exposure into the range set by the values in registers **WPT** (0x3A0F) and **BPT** (0x3A10). For manual speed mode, the step is fixed and supports both normal and fast modes. AEC set to normal mode will allow for the slowest step increment or decrement in the image exposure to maintain the specified range. AEC set to fast mode will provide for an approximate ten-step increment or decrement in the image exposure to maintain the specified range. For auto speed mode, the step will automatically be adjusted according to the difference between the target and present values. The auto ratio of steps can be set by register bits AEC CTRL05[4:0] (0x3A05).

Register HIGH VPT (0x3A11) and register LOW VPT (0x3A1F) controls the fast AEC range in manual speed mode. If the target image AVG (0x5693) is greater than HIGH VPT (0x3A11), AEC will decrease by half. If register AVG (0x5693) is less than LOW VPT (0x3A1F), AEC will double, as shown in **figure 4-7**. These registers have no effect in auto speed mode.

figure 4-7 desired convergence

For the average-based AEC/AGC algorithm, the measured window is horizontally and vertically adjustable and divided by sixteen (4x4) zones (see figure 4-5). Each zone (or block) is 1/16th of the image and has a 4-bit weight in calculating the average luminance (YAVG). The final YAVG is the weighted average of the sixteen zones. The 4-bit weight could be n/16 where n is from 0 to 15.

4.5.3 average luminance (YAVG)

Auto exposure time calculation is based on a frame brightness average value. By properly setting x_start, x_end, y_start, and y_end as shown in **figure 4-8**, a 4x4 grid average window is defined. It will automatically divide each zone into 4x4 zones. The average value is the weighted average of the 16 sections. **table 4-7** lists the corresponding registers.

4.6 AEC/AGC steps

The AEC and AGC work together to obtain adequate exposure/gain based on the current environmental illumination. In order to achieve the best signal-to-noise ratio (SNR), extending the exposure time is always preferred rather than raising the gain when the current illumination is getting brighter. Vice versa, under dark conditions, the action to decrease the gain is always taken prior to shortening the exposure time.

4.6.1 auto exposure control (AEC)

The function of the AEC is to calculate the necessary integration time of the next frame and send the information to the timing control block. Based on the statistics of previous frames, the AEC is able to determine whether the integration time should increase, decrease, fast increase, fast decrease, or remain the same.

In extremely bright situations, the LAEC activates, allowing integration time to be less than one row. In extremely dark situations, the night mode activates, allowing integration time to be larger than one frame.

To avoid image flickering under a periodic light source, the integration time can be adjusted in steps of integer multiples of the period of the light source.

4.6.2 LAEC

If the integration time is only one row period but the image is too bright, AEC will enter LAEC mode. LAEC ON/OFF can be set in register bit 0x3A00[6].

4.6.3 banding mode ON with AEC

In Banding ON mode, the exposure time will fall in steps of integer multiples of the period of light intensity.

Banding ON/OFF can be set in register 0x3A00[5].

For a given light flickering frequency, the band step can be expressed in units of row period.

The band steps for 50Hz and 60Hz light sources can be set in registers {0x3A08[1:0], 0x3A09[7:0]} and {0x3A0A[1:0], 0x3A0B[7:0]}, respectively.

- Banding mode OFF with AEC
- When banding mode is OFF, integration time increases/decreases as normal. It is not necessarily multiples of band steps.

4.6.4 night mode

The OV5647 supports long integration time such as 1 frame, 2 frames, 3 frames, 4 frames, 5 frames, 6 frames, 7 frames, and 8 frames in dark conditions. This is achieved by slowing down the original frame rate and waiting for exposure. Night mode ceiling can be set in register bits 0x3A02[15:8], 0x3A03[7:0]. Night mode can be disabled by setting register bit 0x3A00[2] to 0. Also, when in night mode, the increase and decrease step can be based on band or frames, depending on register 0x3A05[6]. The minimum increase/decrease step can be one band. The step can be based both on bands and frames.

4.6.5 auto gain control (AGC)

Unlike prolonging integration time, increasing gain will amplify both signal and noise. Thus, AGC usually starts after AEC is full. However, in cases where adjacent AEC step changes are too large (>1/16), AGC steps should be inserted in between. The AGC ceiling can be set in {0x3A18[1:0], 0x3A19[7:0]}.

4.7 black level calibration (BLC)

The pixel array contains several optically shielded (black) lines. These lines are used as reference for black level calibration. There are three main functions of the BLC:

- adjusting all normal pixel values based on the values of the black levels
- applying multiplication to all pixel values based on digital gain

table 4-8 BLC control functions

4.8 strobe flash and frame exposure

4.8.1 strobe flash control

The strobe signal is programmable. It supports both LED and Xenon modes. The polarity of the pulse can be changed. The strobe signal is enabled (turned high/low depending on the pulse's polarity) by requesting the signal via the SCCB interface. Flash modules are triggered by the rising edge by default or by the falling edge if the signal polarity is changed. It supports the following flashlight modes (see **table 4-9**).

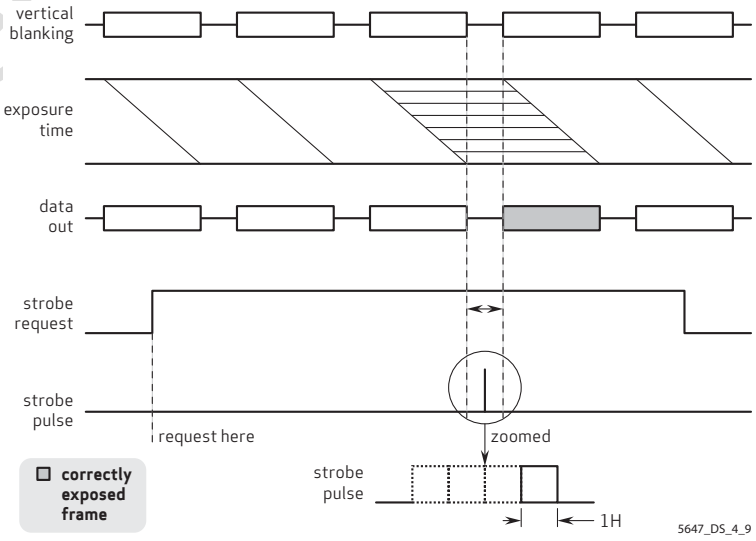
table 4-9 flashlight modes

mode	output	AEC / AGC	AWB
xenon	one-pulse	no	no
LED 1	pulse	no	no
LED 2	pulse	no	yes
LED 3	continuous	yes	yes

4.9 xenon flash control

After a strobe request is submitted, the strobe pulse will be activated at the beginning of the third frame (see **figure 4-9**). The third frame will be correctly exposed. The pulse width can be changed in Xenon mode between 1H and 4H, depending on register 0x3B00[3:2], where H is one row period.

figure 4-9 xenon flash mode



4.9.1 LED1 & 2 mode

Two frames after the strobe request is submitted, the third frame is correctly exposed. The strobe pulse will be activated only one time if the strobe end request is set correctly (see **figure 4-10**). If end request is not sent, the strobe signal is activated intermittently until the strobe end request is set (see **figure 4-11**). The number of skipped frames is programmable using registers {0x3A1C, 0x3A1D}.

figure 4-10 LED 1 & 2 mode - one pulse output

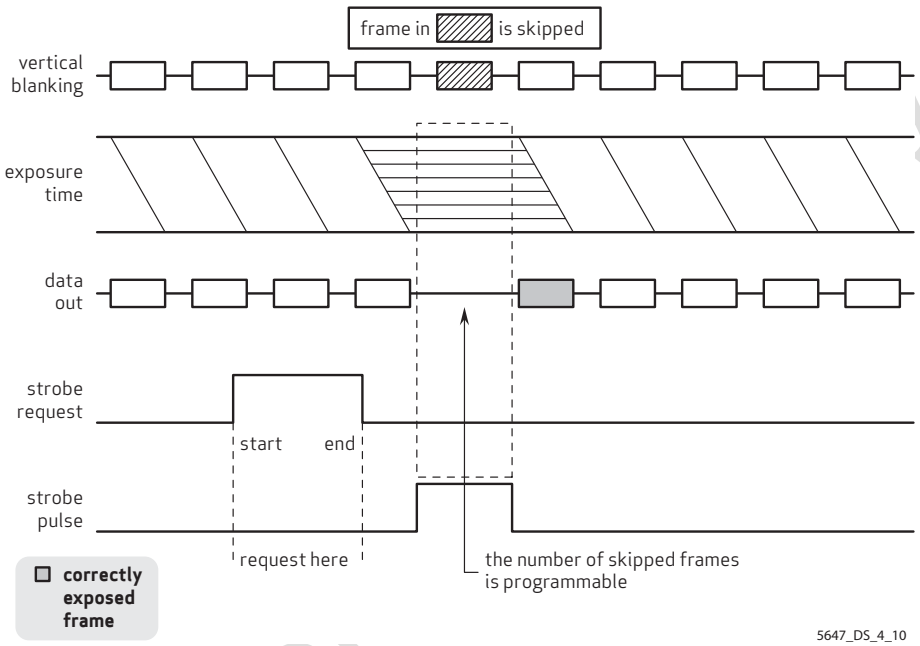


figure 4-11 LED 1 & 2 mode - multiple pulse output

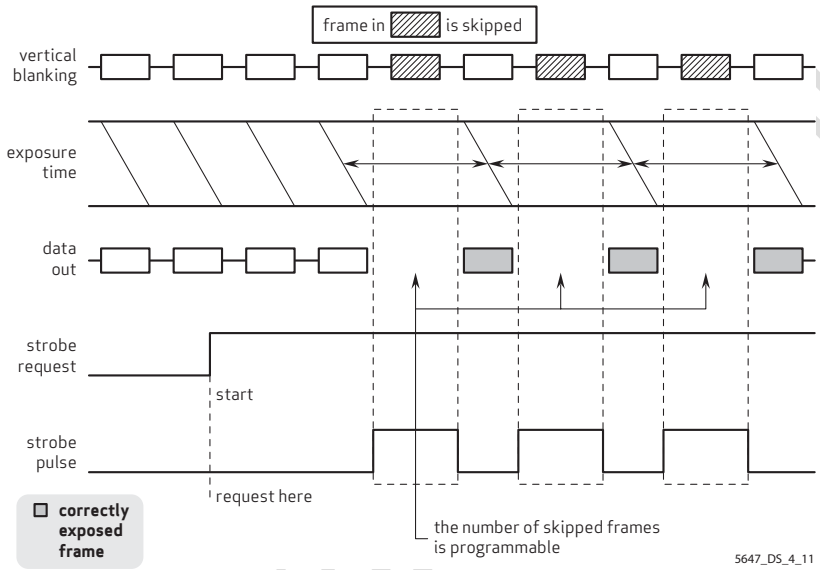
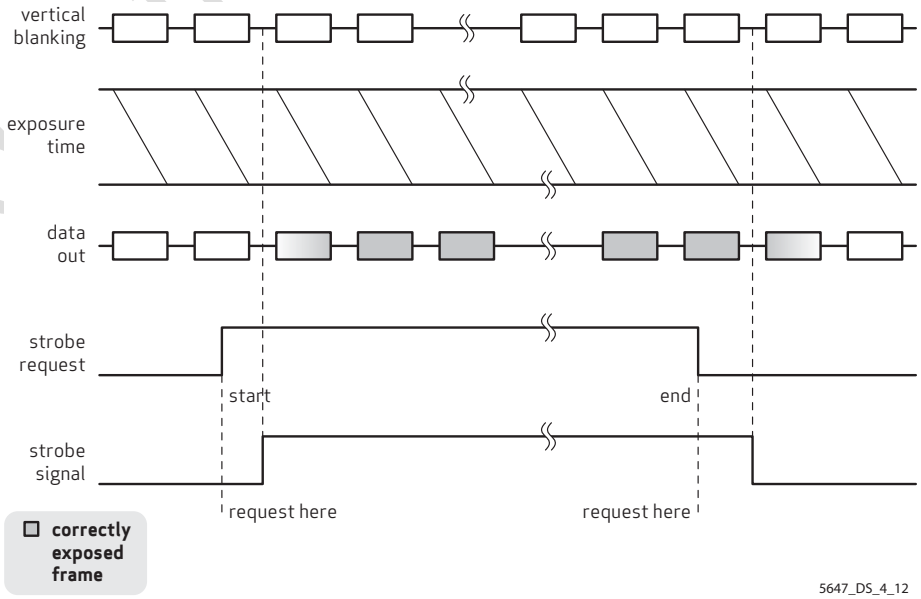


4.9.2 LED 3 mode

In LED 3 mode, the strobe signal stays active until the strobe end request is sent (see figure 4-12).

figure 4-12 LED 3 mode



4.10 frame exposure (FREX) mode

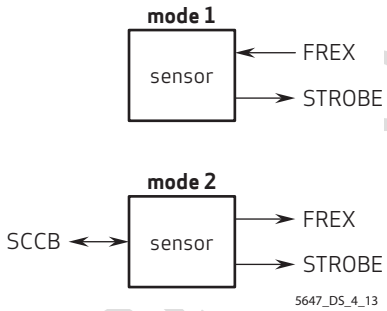
4.10.1 FREX control

In FREX mode, whole frame pixels start integration at the same time, rather than integrating row by row. After the user-defined exposure time (0x3B01, 0x3B04, 0x3B05), the shutter closes, preventing further integration and the image begins to read out. After the readout finishes, the shutter opens again and the sensor resumes normal mode, waiting for the next FREX request.

The OV5647 supports two modes of FREX (see **figure 4-13**):

- mode 1: Frame exposure and shutter control requests come from the external system via the FREX pin. The sensor will send a strobe output signal to control the flash light
- mode 2: Frame exposure request comes from the external system via the SCCB register 0x3B08[0]. The sensor will output two signals, shutter control signal through the FREX pin and strobe signal through the STROBE pin

figure 4-13 FREX modes



In mode 1, the FREX pin is configured as an input while it is configured as an output in mode 2. In both mode 1 and mode 2, the strobe output is irrelevant with the rolling strobe function. When in rolling shutter mode, the strobe function and this FREX/shutter control function do not work at the same time.

4.11 FREX strobe flash control

See **table 4-10** for FREX strobe control functions.

5.2 lens correction (LENC)

The main purpose of the LENC is to compensate for lens imperfection. According to the area where each pixel is located, the module calculates a gain for the pixel, correcting each pixel with its gain calculated to compensate for the light distribution due to lens curvature. The LENC correcting curve automatic calculation according sensor gain is also added so that the LENC can adapt with the sensor gain. Also, the LENC supports the subsample function in both horizontal and vertical directions.

Registers 0x5888 ~ 0x588F need to change only when DSP input is not generated internally. In other words, the DSP input is from an external sensor.

5.3 defect pixel cancellation (DPC)

Due to processes and other reasons, pixel defects in the sensor array will occur. Thus, these bad or wounded pixels will generate wrong color values. The main purpose of Defect Pixel Cancellation (DPC) function is to remove the effect caused by these bad or wounded pixels. Also, some special functions are available for those pixels located at the image boundary. To remove the defect pixel effect correctly, the proper threshold should first be determined.

table 5-3 defect pixel cancellation registers

0x5780~ 0x5791	DPC CTRL	–	RW	Debug Control Changing these registers is not recommended

5.4 auto white balance (AWB)

The main function of Auto White Balance (AWB) is the process of removing unrealistic color casts so that objects which appear white in person are rendered white in the image or video. Thus, the AWB makes sure that the white color is always a white color in different color temperatures. It supports manual white balance and auto white balance. For auto white balance, simple AWB is supplied. For auto white balance, the adjust option is also provided for the customer.

6.8 mobile industry processor interface (MIPI)

MIPI provides a single uni-directional clock lane and two bi-directional data lane solution for communication links between components inside a mobile device. The two data lanes have full support for HS (uni-directional) and LP (bi-directional) data transfer mode.

table 6-9 MIPI transmitter registers (sheet 1 of 8)

8 operating specifications

8.1 absolute maximum ratings

table 8-1 absolute maximum ratings

parameter		absolute maximum rating[a]
ambient storage temperature		-40°C to +125°C
supply voltage (with respect to ground)	V_{DD-A}	4.5V
	V_{DD-D}	3V
	V_{DD-IO}	4.5V
electro-static discharge (ESD)	human body model	2000V
	machine model	200V
all input/output voltages (with respect to ground)		-0.3V to V_{DD-IO} + 1V
I/O current on any input or output pin		±200 mA

a. exceeding the absolute maximum ratings shown above invalidates all AC and DC electrical specifications and may result in permanent damage to the device. Exposure to absolute maximum rated conditions for extended periods may affect device reliability.

8.2 functional temperature

table 8-2 functional temperature

parameter	range
operating temperature range[a]	-30°C to +70°C
stable image temperature range[b]	0°C to +50°C

a. sensor functions but image quality may be noticeably different at temperatures outside of stable image range

b. image quality remains stable throughout this temperature range

8.3 DC characteristics

table 8-3 DC characteristics (-30°C < T_A < 70°C)

symbol	parameter	min	typ	max	unit
supply					
V_{DD-A}	supply voltage (analog)	2.6	2.8	3.0	V
V_{DD-DO}	supply voltage (digital I/O)	1.7	1.8	3.0	V
V_{DD-D}	supply voltage (digital core)[a]	1.425	1.5	1.575	V
V_{DD-E}	supply voltage (MIPI)	1.425	1.5	1.575	V
I_{DD-A}	active (operating) current 2592 x 1944 @ 15 fps[b]		TBD	TBD	mA
I_{DD-DO}			TBD	TBD	mA
I_{DD-A}	active (operating) current 720p @ 30fps		TBD	TBD	mA
I_{DD-DO}			TBD	TBD	mA
I_{DD-A}	active (operating) current 720p @ 60fps		TBD	TBD	mA
I_{DD-DO}			TBD	TBD	mA
I_{DD-A}	active (operating) current VGA @ 30fps		TBD	TBD	mA
I_{DD-DO}			TBD	TBD	mA
I_{DD-A}	active (operating) current VGA @ 60fps		TBD	TBD	mA
I_{DD-DO}			TBD	TBD	mA
$I_{DDS-SCCB}$[c]	standby current		TBD	TBD	µA
$I_{DDS-PWDN}$			TBD	TBD	µA
digital inputs (typical conditions: AVDD = 2.8V, DVDD = 1.5V, DOVDD = 1.8V)					
V_{IL}	input voltage LOW			0.54	V
V_{IH}	input voltage HIGH	1.26			V
C_{IN}	input capacitor			10	pF
digital outputs (standard loading 25 pF)					
V_{OH}	output voltage HIGH	1.62			V
V_{OL}	output voltage LOW			0.18	V
serial interface inputs					
V_{IL}[d]	SCL and SDA	-0.5	0	0.54	V
V_{IH}[d]	SCL and SDA	1.26	1.8	2.3	V

a. when internal regulator is bypassed

b. using internal regulator for DVDD and short DVDD with EVDD; DOVDD = 2.8V. The currents are for DVP output. MIPI output will results 5%-10% lower active current on I_{DD-DO}

c. external clock is stopped during measurement

d. based on DOVDD = 1.8V

8.4 AC characteristics

table 8-4 AC characteristics (T_A = 25°C, V_{DD-A} = 2.8V)

symbol	parameter	min	typ	max	unit
ADC parameters					
B	analog bandwidth		48		MHz
DLE	DC differential linearity error		0.5		LSB
ILE	DC integral linearity error		1		LSB
	settling time for hardware reset			<1	ms
	settling time for software reset			<1	ms
	settling time for resolution mode change			<1	ms
	settling time for register setting			<300	ms

table 8-5 timing characteristics

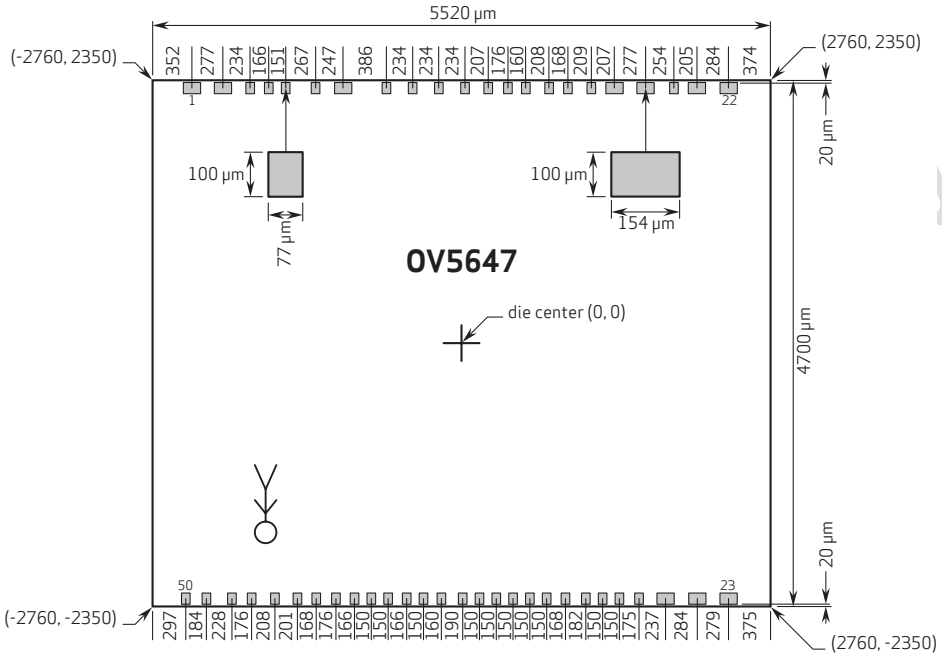
symbol	parameter	min	typ	max	unit
oscillator and clock input					
f_{OSC}	frequency (XCLK)	6	24	27	MHz
t_r, t_f	clock input rise/fall time			5 (10[a])	ns

a. if using the internal PLL

9 mechanical specifications

9.1 physical specifications

figure 9-1 die specifications



note 1 all dimensions and coordinates are in µm.
